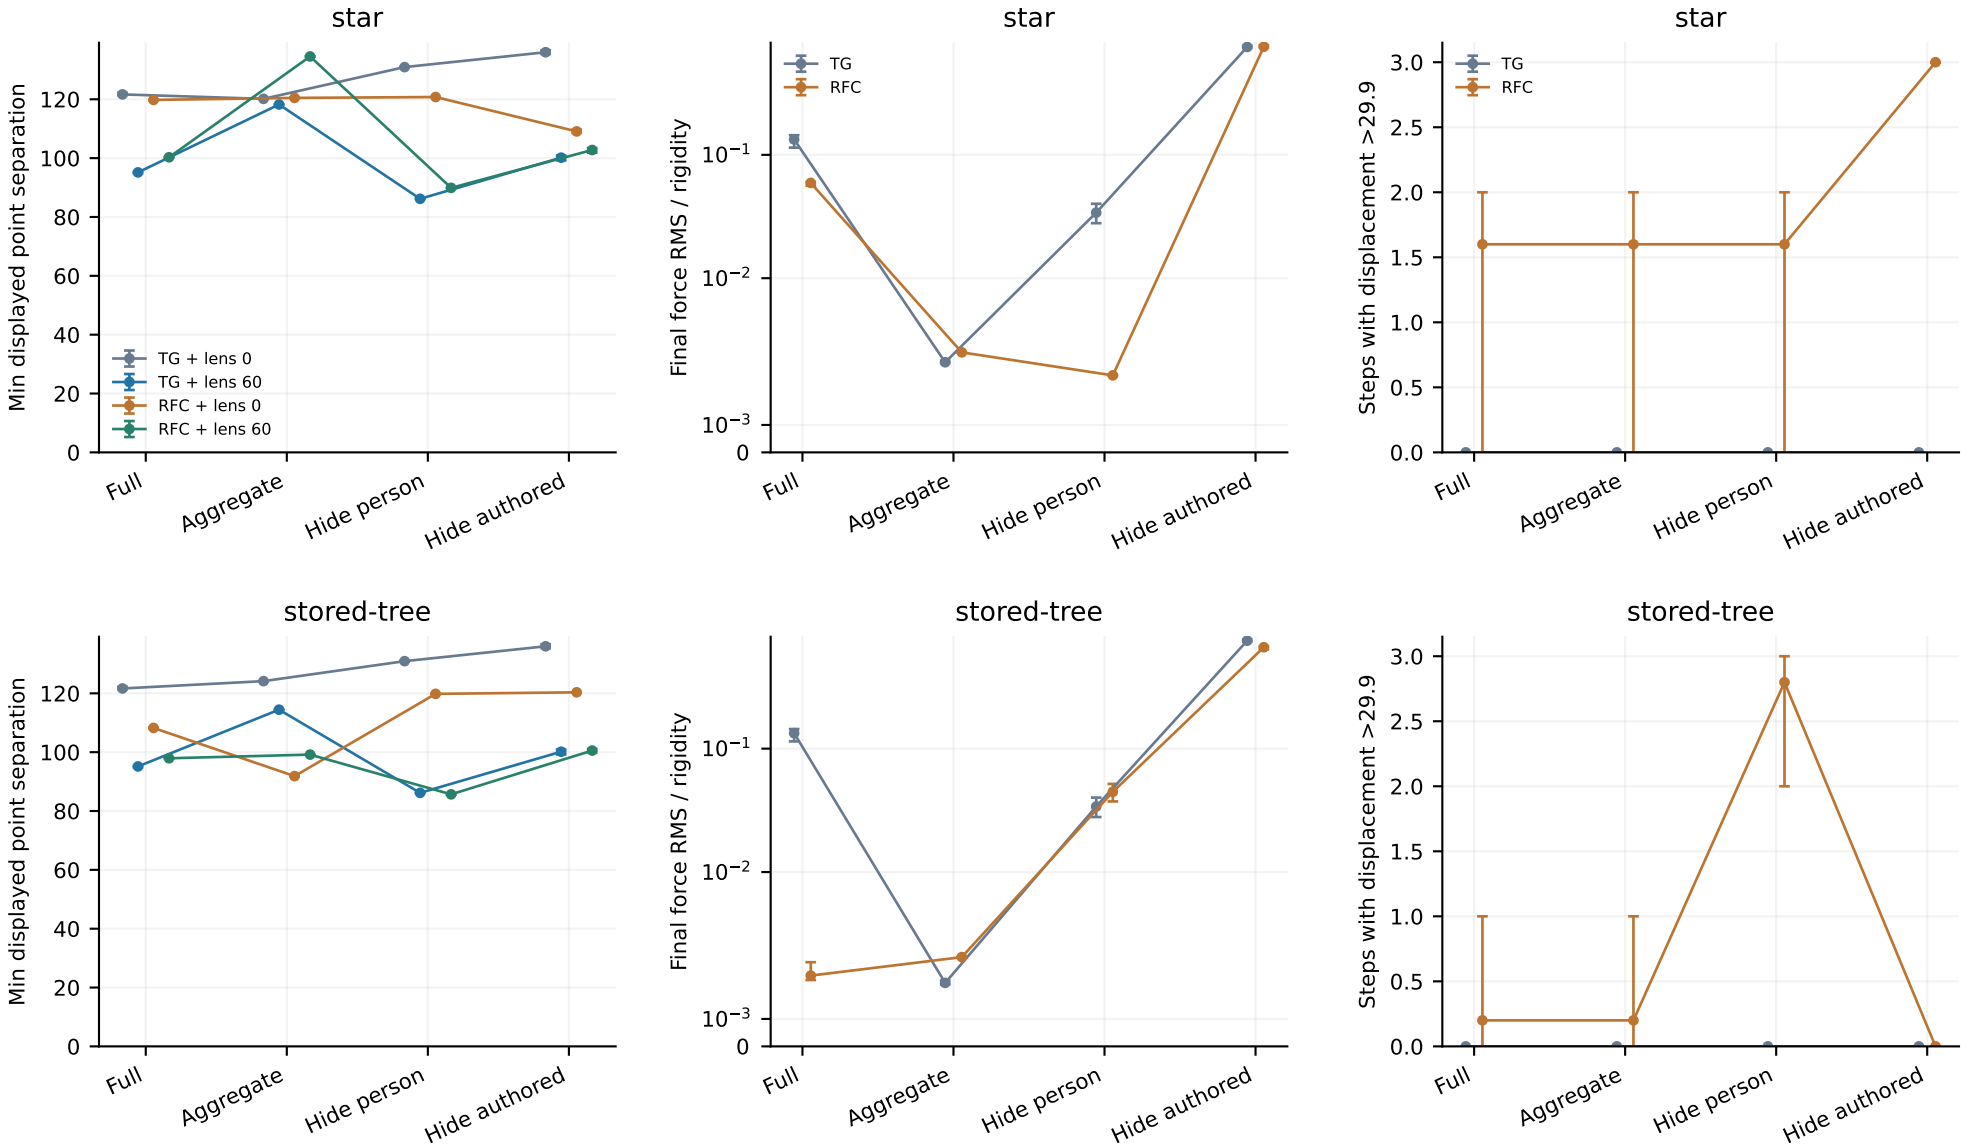
# J3. Lens separation, remaining net force and transient movement



J3. Means and min–max across five starts; physical metrics use lens-zero runs once, while the left column includes both lens twins. Point separation is measured on each visible view, with node/edge/pair denominators in the report; it is not a readability score or a common-subset ranking. All runs have zero last-100-step motion after TG global cooling, yet force imbalance remains, especially when authored-link filtering leaves four isolated paper nodes. Large steps are counted over every integration and are distinct from per-axis clipping. Sparse straight-line and close-pair proxies are zero at the end of every condition here and cannot discriminate quality.
