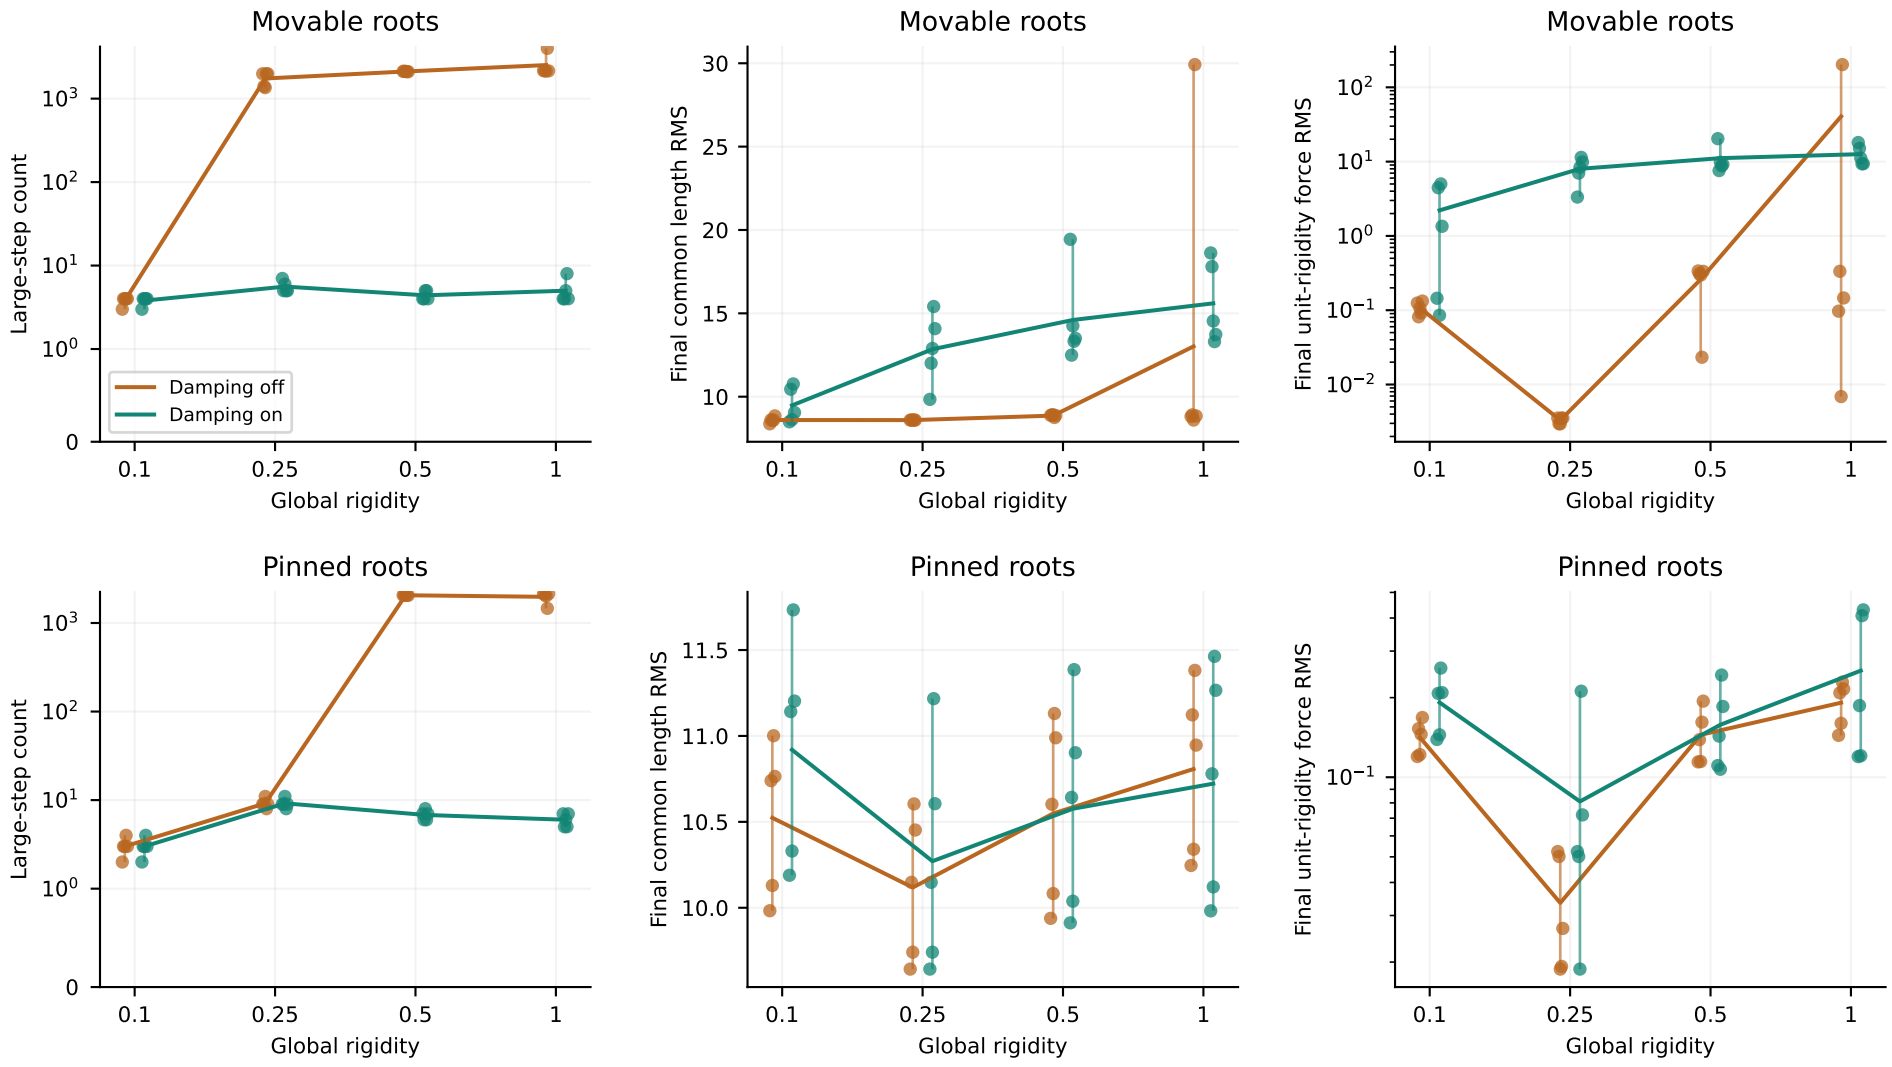
F1. Lower rigidity versus adaptive damping: leaf-linked trees



F1. Five identical seeded starts per condition, 4000 integrations. Points are individual starts, lines are means and verticals span min–max, not confidence intervals. Lower rigidity changes all force magnitudes from the first integration. Force is probed without momentum/local attenuation and divided by rigidity; values below 1e-6 are floored for display. Quiet motion does not imply force balance or accurate lengths.
